A brief explanation of the software issue(s) you fixed in the notebook:

The notebook was using mse and mae, which are more for regression. Since this lab is classifying two gestures, I changed the loss to categorical_crossentropy and the metric to accuracy.

Any important changes you made to make the notebook, plots, metrics, or model export consistent:

I also changed the plot metric from mae to accuracy so the training graph matches the classification task. After that, the notebook trained the model, evaluated it with accuracy, converted it to TFLite, and exported it as model.h.
